## **SUGGESTED CITATION :**

Cavitt, J. F., S. L. Jones, N. M. Wilson, J. S Dieni, T. S. Zimmerman, R. H. Doster, and W. H. Howe. 2014. Atlas of breeding colonial waterbirds in the interior western United States. Research Report, U.S. Department of the Interior, Fish and Wildlife Service, Denver, Colorado.

## INTRODUCTION

Colonial waterbirds comprise a diverse assemblage of species that share important characteristics of ecology and natural history. Waterbirds within this group depend on specific and often limited aquatic habitats for much of their life cycles, and generally breed in high-density groups or colonies, ranging from a few to several thousand individuals. Coloniality within this group likely evolved independently within the different taxa and as a response to various environmental pressures (Burger 1981, Forbes 1989, Rolland et al. 1998). This behavior poses important challenges to waterbird conservation because large proportions of a species population may be concentrated in relatively small isolated areas (Kushlan et al. 2002).

In the arid interior west, colonies occur in relatively few locations. Western breeding habitats include wooded and barren islands, riparian corridors, marshes, seasonal wetlands, managed impoundments and open waters. Many of these aquatic habitats within the western United States are strongly influenced by human activities, resulting in their loss or degradation. Factors responsible for losses and degradation include water diversions, damming, filling, draining, flooding, eutrophication, contaminant concentrations, and agricultural activities, e.g., haying, tilling, and pesticide use. Numerous studies have demonstrated that these and other factors can affect the suitability of nesting and brood-rearing sites for colonial waterbirds (e.g. Catsadorakis et al. 1996, Naugle et al. 2000, Smith et al. 2003). Furthermore, the climatic regime of the western U.S. including long-term drought, coupled with an increasing demand for water resources by human populations, often results in changing aquatic habitat conditions between years. Because of the transitory nature of many of these western aquatic habitats, waterbird colonies can also be transitory, persisting only until the habitats become unsuitable; some species and large colonies will greatly alter nesting locations from year-to-year. This results in an inherent variability of local breeding populations. Their characteristic breeding behavior together with the reliance on often limited and impacted aquatic habitats (Shuford 2010) make colonial waterbirds particularly vulnerable to disturbance and loss of breeding sites.

Coupled with these challenges to waterbird conservation are the increasing effects of global climate change. In general, there has been a trend towards earlier spring arrival and breeding of many waterbird species (e.g. Crick and Sparks 1999, La Sorte and Thompson 2007, Swanson and Palmer 2009, Cox 2010) which could lead to a disconnect between habitat, including food resources, and nesting timing. Furthermore, the breeding, migratory stopover and nonbreeding habitats for many waterbirds are particularly vulnerable to climate change (Cox 2010). Increased temperatures will likely lead to reduced soil moisture causing the loss or reduction of many wetlands (e.g. Johnson et al. 2005).

Consequently, many of these species are targets of conservation efforts throughout North America (Kushlan et al. 2002, Drilling 2007, U.S. Fish and Wildlife Service 2008). Others within this group are experiencing population increases and expanding their distribution (Table 1), resulting in escalating conflicts with agriculture and fisheries (Kushlan et al. 2002) and human residential areas.

Despite their importance and conservation status in the west, no systematic inventory of waterbird colonies has been conducted in this region. This lack of information has greatly impeded the ability of biologists and conservationists to manage this group of birds (Drilling 2007, Seto 2008). Thus, many western states identified information on the distribution and abundance of colonial waterbirds as a conservation priority. This included acquiring abundance and distribution data to determine population status and to identify priority conservation regions and actions (e.g. Montana Fish, Wildlife and Parks 2005). Current distribution and abundance information on western colonial nesting waterbirds is needed for conserving populations, resolving management conflicts stemming from increasing and expanding populations, and providing the data necessary to manage waterbird populations at the local and regional scale (Seto 2008). These concerns resulted in a comprehensive survey throughout the west.

From 2009 through 2011, U.S. Fish and Wildlife Service Regions 1 (Pacific), 2 (Southwest), 6 (Mountain-Prairie), 8 (Pacific-Southwest), and 9 (National Headquarters), together with biologists from the interior western states designed and implemented a survey to inventory and document the status of these species (Seto 2008). The Western Colonial Waterbird Survey (WCWS) and resulting *Atlas of Breeding Colonial Waterbirds in the Interior Western United States* (Atlas) were designed primarily to provide biologists, resource managers, regulatory agencies, and researchers with the best available data on the size and location of inland western waterbird colonies, in a standardized format. This Atlas presents summary results of surveys conducted in the eight participating interior western states (Figure 1). A summary atlas of WCWS survey results for the three participating Pacific Coastal states is currently in preparation (M. McDowell and N. Seto, pers. comm.). The information compiled here serves as a baseline of recent and available historical distribution and abundance. Finally, future surveys and monitoring can be planned using these data as a comprehensive baseline inventory and atlas of these colonies.

## OBJECTIVES

The objectives of the WCWS were to conduct a comprehensive inventory of waterbird breeding sites and populations in the western United States. Specific objectives included:

- 1) Document the species composition, size, and location of breeding colonies from 2009 through 2011.
- 2) Produce an atlas of western colonial waterbird breeding colonies. This included an inventory and mapping of current (2009-2011) colonies, compiling existing information on historical sites (where available) and locating and mapping new colonies.
- 3) Establish a baseline for the development of a long-term monitoring program for colonial waterbirds in the west.
- 4) Estimate the minimum regional population size of breeding waterbirds.

## METHODS

*Species.* —The coordinators for the WCWS selected 18 target species from six families (scientific names are in Table 1); Neotropic Cormorant was added later for Arizona and New Mexico to account for this species' increasing occurrence throughout the southwest. These 19 species were the primary colonial nesting waterbird species in the west at the time of the survey; other waterbirds that are primarily solitary breeders (e.g., Pied-billed Grebe, *Podilymbus podiceps*) were not included in this effort.

*Geographic Coverage.* —This Atlas contains the WCWS results from the eight interior western states: Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Utah, and Wyoming (Figure 1).

*Season.* —The WCWS was a breeding survey, and for the most part, surveys were conducted in May-July. The optimal timing for the survey was an important consideration and thus was locally determined to account for the peak of waterbird breeding in each state. The criterion for each state was for the counting period to occur during the mid- to late-incubation period for each species. Only one colony count per year was recommended with surveys conducted at approximately the same time or within the same point of the nesting cycle every year (Jones 2008).

*Parameters.* —The primary parameters for the WCWS were the number of active breeding individuals and active nests. Because nests for many species may persist from year to year but may not be reused, each nest was quickly evaluated for activity during survey periods (Jones 2008). Active nests were defined as nests with

eggs or chicks, incubating or brooding adults, nests with fledged chicks present, or nests that were otherwise being tended by adults, such those that were under construction or being repaired. An inactive nest was either an old nest not used in the present year, or a nest abandoned early in the season (Jones 2008).

*Detectability.* —The WCWS had two detectability concerns. The first involved determining the location of colonies. Because this project included a large geographic area, surveyors could potentially miss colony locations. To assist in reducing this concern, state coordinators used historical data, breeding bird atlases, and local experts in an attempt to locate all previously known colonies. One of the objectives for the survey was to locate previously unknown colonies. Surveyors were asked to balance efficiency of effort and resources with good coverage to locate these potential colony sites (Jones 2008). A second detectability issue was missing nests within colonies. This could potentially be a problem within large, dense colonies or because the timing of the survey was incorrect for the target species or survey year. In an attempt to minimize this concern, we utilized protocols that have been demonstrated to be successful for a wide variety of species and habitats surveyed (Steinkamp et al. 2003).

*Colony and Regional Population Estimates.* —Direct nest counts were used whenever possible (Steinkamp et al. 2003). Colony counts based on direct nest counts provide more accurate information than counting total number of adults. Adult counts can be biased as they may contain both breeding and non-breeding individuals. In addition, direct counting of adults is easy with large birds at close range, but becomes progressively more difficult with larger numbers, smaller species, and greater distances (Jones 2008). Consequently, a direct nest count was suggested whenever possible. Population estimates (without correction factors) can be derived from this inventory, but these will not be based on sampling and inferential statistics at the population level. The colony population sizes presented within this Atlas are likely conservative and underestimates of true population size. Correction factors for colonies using the estimate of colony size, per species, can be taken from the published literature (if needed) to account for breeding birds away from the colony and for non-breeding birds present in the colony. The regional population estimates (without correction factors) derived from this inventory are also minimum population estimates.

*Protocol.* —The protocol or methodology and parameters depended on resources available, species, habitat, colony size, presence of predators, accessibility, ability to find nests within the vegetation, and the number of people available to conduct the survey. All of these considerations were also balanced with the ability of surveyors to collect data without causing unacceptable levels of disturbance to nesting birds and vegetation. Detailed protocols were recommended for those sites that were not

currently being counted, and where established protocols did not exist (Jones 2008). These protocols were also considered as an alternative to ongoing surveys where local or subject area experts determined they were appropriate (Jones 2008).

## **INTERIOR WESTERN COLONIAL WATERBIRD ATLAS**

The Atlas consists of two parts: the maps for all the sites surveyed during the WCWS and a data table (Atlas Tables). In addition to the Atlas, the final data includes the survey data for each state (State Databases).

*State Databases.* —All data from the WCWS were entered into Microsoft EXCEL spreadsheets, one for each state. Each spreadsheet has three parts: 1) Breeding birds; 2) Nonbreeding, if collected in that state. AZ, ID and NM did not generally collect nonbreeding data; however, there were some records that were nonbreeding and were included; and 3) historical data, if compiled for that state. Historical data are incomplete in many states, e.g., MT did not compile historical data from before 2009. The purpose of these State Databases is to allow summary and location data to be available in an accessible format. The breeding bird data sheets are the data collected during the WCWS (2009-2011) and are the data that were used to produce the maps for the Atlas. In producing the Atlas Tables, if more than one visit to any one site was completed in the same year, the Atlas Table records only the record with the maximum numbers of individuals or the record identified as the most recent, accurate or representative when such data were provided. In the State Databases, all records were recorded.

*Survey Summary.* —Data were combined into a single spreadsheet file for error checking, correction and analysis. All statistical analyses were conducted using SPSS (SPSS Inc. 2008). Variables and data were inspected using a combination of cross tabulation and frequency tables to search for misspellings, missing data, discrepancies, improper cell formatting, and data inconsistencies. We summarized the following variables for breeding birds: estimates of the number of breeding individuals in total and for each state. The maximum value obtained across all visits and years for the WCWS was used for colonies that had been counted more than once. All variables except for count data were treated as nominal-level measurements.

*Table Construction and Mapping.* —Data were compiled and proofed by each state coordinator and survey coordinators. Data were then prepared into corresponding tables for each state. The Universal Transverse Mercator (UTM) coordinates for each site were recorded and mapped using base maps from ArcGIS (Environmental Systems Research Institute 2012). In an attempt to avoid disturbance to active colonies, the UTM coordinates provided often represent the location of the observer

rather than the location of the colony itself. Typically, when multiple surveys were conducted for each site within a single breeding season, the highest colony counts for each species were reported and are recorded in the tables.

*How to Use This Atlas.* —The Atlas is divided into eight state sections. Each state section contains maps depicting the locations of colonies, as well as tables of recent and historical data (only for the colonies still active during the WCWS) throughout the state. We have included several different maps which contain information about state land ownership, colony location and colony size or density. The first map of each state section is the state's land ownership map overlaid with the location of all colonies recorded for this atlas. The second map provides the "Area" name for each of the USGS 1:250,000 topographic maps covering the state. Colony locations for the state were overlaid on these maps to provide a reference for the reader. The colony tables are then arranged within each Area subsection. The Area subsections include an Area map, as an index to locations, and the relative densities of waterbird colonies. The pages following this map include colony data tables and detailed maps of colony locations. The accompanying tables present the recent and historical (where available) counts of the number of breeding birds, for each species, at each colony.

*Colony Numbers and Names.* —Colonies were assigned unique identifying numbers during the WCWS and Atlas development. USGS maps were sequentially numbered for the conterminous United States and served as the basis for the standardized colony number system (Spendelov and Patton 1988, Naughton et al. 2007). Within each state area, colonies were numbered sequentially from north to south with the first seven characters representing the map number and the last three digits representing the colony number, beginning with 001 (Naughton et al. 2007). Colony names were derived from maps or charts whenever possible.

*Atlas Data Tables.* —The data on the following tables contain the recent estimates of colony size, and include the current abundance and distribution of breeding colonial waterbirds within the state. Data from the WCWS (2009-2011) were used to generate the maximum total statewide counts for each species. Figures 2a and 2b provide an example of a data table with an explanation of the columns and codes. Historical data are provided where available; however, for many states this is the first statewide estimate of breeding colonial waterbird populations.

## RESULTS

### INTERIOR WESTERN COLONIAL WATERBIRD ATLAS

The Atlas, consisting of the maps, data tables and state databases described here, are available on the internet; addresses and contacts are provided in Table 2.

### SURVEY SUMMARY

Overall, 19 colonial waterbird species from four orders and six families were identified across eight western U.S. states (Table 1). Members of the family Laridae were collectively the most abundant, accounting for about 60% of all breeding individuals (Table 3). This family also had the most species ( $N=7$ ). Interestingly, Threskiornithidae, comprising just a single species (White-faced Ibis), was the second most abundant family (22%). Members of the family Ardeidae, largely driven by Great Blue Herons, were collectively the most frequently occurring species (55%).

We recorded over 605,000 breeding individuals. Nearly 45% of these were recorded in Idaho, followed by 31% in Utah (Table 4). In contrast, < 1% was recorded in New Mexico and Wyoming. We identified 1,255 breeding colonies among all species; 23% in Montana, followed by 20% in Utah. Again, we observed relatively few breeding colonies in Wyoming (6%) or New Mexico (4%). Utah had the most breeding species ( $N=17$ ), Arizona the fewest ( $N=8$ ).

Across the region, California (27%) and Franklin's (26%) gulls, White-faced Ibis (23%), American White Pelican (7%) and Ring-billed Gull (6%) were the most abundant species, comprising 89% of all identified breeding birds (Figure 3; Table 5). The largest colony occurred at the Great Salt Lake at Hat Island in Utah with nearly 36,000 breeding California Gulls in 2010. Idaho had the next two largest colonies: ca. 32,000 (Gray's Lake National Wildlife Refuge) and ca. 29,000 (Market Lake Wildlife Management Area), both for Franklin's Gull in 2010. A 24,500-sized colony of breeding White-faced Ibis was also observed at Market Lake that year. Great Blue Herons represented 2% of all breeding individuals but accounted for 39% of all colonies, the most for any species. Moreover, this species was the most frequent colony in seven of eight states. (White-faced Ibis got the top honors in Nevada, accounting for 24% of all colonies in that state.)

State-level statistics for each identified species are provided in Table 6.

## ACKNOWLEDGMENTS

This publication is result of the hard work of many dedicated biologists and resource managers working throughout the western states. The 2009-2011 WCWS and the Atlas were made possible with funding, staff, and logistic support provided by the U.S. Fish and Wildlife Service, Regions 1, 2, 6, 8, and 9, the American Bird Conservancy, Weber State University and State natural resources or fish and wildlife agencies in the eight interior western states.

Special thanks goes to N. E. Drilling of Rocky Mountain Bird Observatory for allowing the use of her South Dakota work in the development of this survey, as well as to N. W. H. Seto (USFWS) for working on the initial concept and J. A. Wheeler (USFWS) who was involved in all aspects of the planning of the survey. We are grateful to the many reviewers of the initial survey: J. Bruce, A. Orabona, L. Comrack, T. Corman, N. E. Drilling, S. D. Fellows, J. Hansen, L. Henkel, G. L. Ivey, C. Moulton, J. Neill, A. Puchniak Begley, W. D. Shuford, V. Steen, and D. Withers.

Federal and state biologists who coordinated the survey include J. Beason, D. Hanni, and D. Klute (CO), T. Corman (AZ), C. Moulton (ID), J. Neill (UT-GSL), J. F. Cavitt (UT), A. Orabona (WY), C. Wightman (MT), H. Walker (NM), J. Hoskins, N. W. H. Seto, and T. S. Zimmerman (R1, USFWS), W. H. Howe (R2, USFWS), S. L. Jones (R6, USFWS), R. H. Doster (R8, USFWS), and B. Altman of American Bird Conservancy. Many biologists and volunteers contributed data to the Western Colonial Waterbird Survey; a list of contributors are in Appendix A. ([http://www.fws.gov/mountain-prairie/species/birds/western\\_colonial/Appendix\\_A.pdf](http://www.fws.gov/mountain-prairie/species/birds/western_colonial/Appendix_A.pdf)).

Databases were compiled and corrected by S. L. Jones, N. M. Wilson, J. F. Cavitt, J. S. Dieni, and Trina Nixon. This report benefited by helpful reviews from J. Neill, and J. A. Wheeler. J. F. Cavitt and the Avian Ecology Lab at Weber State University developed and managed the GIS colony location databases and produced the colony maps and tables. Crystal Wikstrom and Justin Williamson developed and produced the maps and Tess Woodward provided the graphic design and layout of the Atlas. Partial funding to compile this Atlas was provided by U.S. Fish and Wildlife Service, Division of Migratory Birds and Habitat Programs, Mountain Prairie Region, Denver, CO through the efforts of Casey Stemler, and the Division of Migratory Bird Management, Arlington, VA through the efforts of J. A. Wheeler. The findings and conclusions in this publication are those of the authors and do not necessarily represent the views of the U.S. Fish and Wildlife Service.

**Table 1.** Bird species targeted during the Western Colonial Waterbird Survey (2009-2011) across eight western interior U.S. states, listed taxonomically by order, family and subfamily (American Ornithologists' Union 1998).

Order	Family	Subfamily	Common Name	Scientific Name
Podicipediformes	Podicipedidae		Eared Grebe	<i>Podiceps nigricollis</i>
			Western Grebe	<i>Aechmophorus occidentalis</i>
			Clark's Grebe	<i>A. clarkii</i>
Suliformes	Phalacrocoracidae		Neotropic Cormorant	<i>Phalacrocorax brasilianus</i>
			Double-crested Cormorant	<i>P. auritus</i>
Pelecaniformes	Pelecanidae		American White Pelican	<i>Pelecanus erythrorhynchos</i>
		Ardeidae	Great Blue Heron	<i>Ardea herodias</i>
	Great Egret		<i>A. alba</i>	
	Snowy Egret		<i>Egretta thula</i>	
	Cattle Egret		<i>Bubulcus ibis</i>	
	Black-crowned Night-Heron		<i>Nycticorax nycticorax</i>	
	Threskiornithidae	Threskiornithinae	White-faced Ibis	<i>Plegadis chihi</i>
Charadriiformes	Laridae	Larinae	Franklin's Gull	<i>Leucophaeus pipixcan</i>
			Ring-billed Gull	<i>Larus delawarensis</i>
			California Gull	<i>L. californicus</i>
		Sterninae	Caspian Tern	<i>Hydroprogne caspia</i>
	Black Tern		<i>Chlidonias niger</i>	
	Common Tern		<i>Sterna hirundo</i>	
	Forster's Tern		<i>S. forsteri</i>	

**Table 2.** Location (internet addresses and contact information) of the state maps and tables for the *Atlas of Breeding Colonial Waterbirds in the Interior Western United States* and state databases.

Counts/estimates of nests or birds

What was counted (W) to generate the estimated # of breeding birds  
 N = Nests  
 NP = Nests or pairs  
 P = Pairs  
 B = Individuals  
 O = No quantitative estimate  
 U = Unknown

Conversion Factor (Cnv)  
 Counts of birds or nests were multiplied by this value to generate the estimated # of breeding birds  
 L = No conversion  
 2 = Nests x 2  
 A = Midpoint of range  
 J = Adjusted by manager  
 S = Extrapolation from sample plots

Boxed data at the top of the table indicates the most recent, accurate, or representative data for this colony. Historical data are listed below.

Survey Type (ST)  
 A = Aerial  
 AP = Aerial Photography  
 B = Boat  
 C = Ground Survey in colony  
 O = Overview vantage point  
 U = Unknown

Estimate Type (T)  
 W = Direct Count  
 S = Sample (e.g. density sampled in plots)  
 Z = Partial count, rest estimated  
 T = Count by groups (e.g. 100s or 1000s)  
 K = Count adjusted by observer  
 Y = Estimate, not a direct count  
 X = Confirmed breeding, no count  
 P = Probable breeding, no count  
 V = Breeding birds common or abundant  
 U = Unknown

**Figure 2a.** Key to data tables and codes used in the maps in the *Atlas of Breeding Colonial Waterbirds in the Interior Western United States*.

**Data Codes.** Codes used within the site tables are defined below.

**Universal Transverse Mercator.**--The geographic coordinates for each colony are presented as Universal Transverse Mercator (UTM). The format for each location is presented in zone number, letter, easting and northing.

**What Counted (W).**--What was counted, birds or nests.

<u>Code</u>	<u>Description</u>
B	Birds: count or estimate of individual birds in colony.
N	Nests: count or estimate of nests in colony.
NP	Nests or Pairs: count or estimate of nests or breeding pairs.
P	Pairs: count or estimate of breeding pairs in colony.
O	No count or estimate: observer provided no quantitative estimate of colony size, only non-numeric data like "Present" or "Rare".
U	Unknown: unexplained how the number was generated.

**Conversion (Cnv).**--This code describes how the count or survey data were adjusted to generate estimates of breeding birds. Counts of nests were multiplied by 2 and counts of birds were often adjusted by a conversion factor to account for non-breeding birds at the colony and breeding birds away from the colony.

<u>Code</u>	<u>Description</u>
L	Literal count or estimate reported by observers; no adjustment.
2	Counts of nests were multiplied by 2 to estimate the number of breeding birds.
A	Midpoint of range (e.g., 500-1000 entered as 750).
J	Manager adjusted observer's data another way.
S	Extrapolation of data from sampling (e.g., nest densities in sample quadrats).

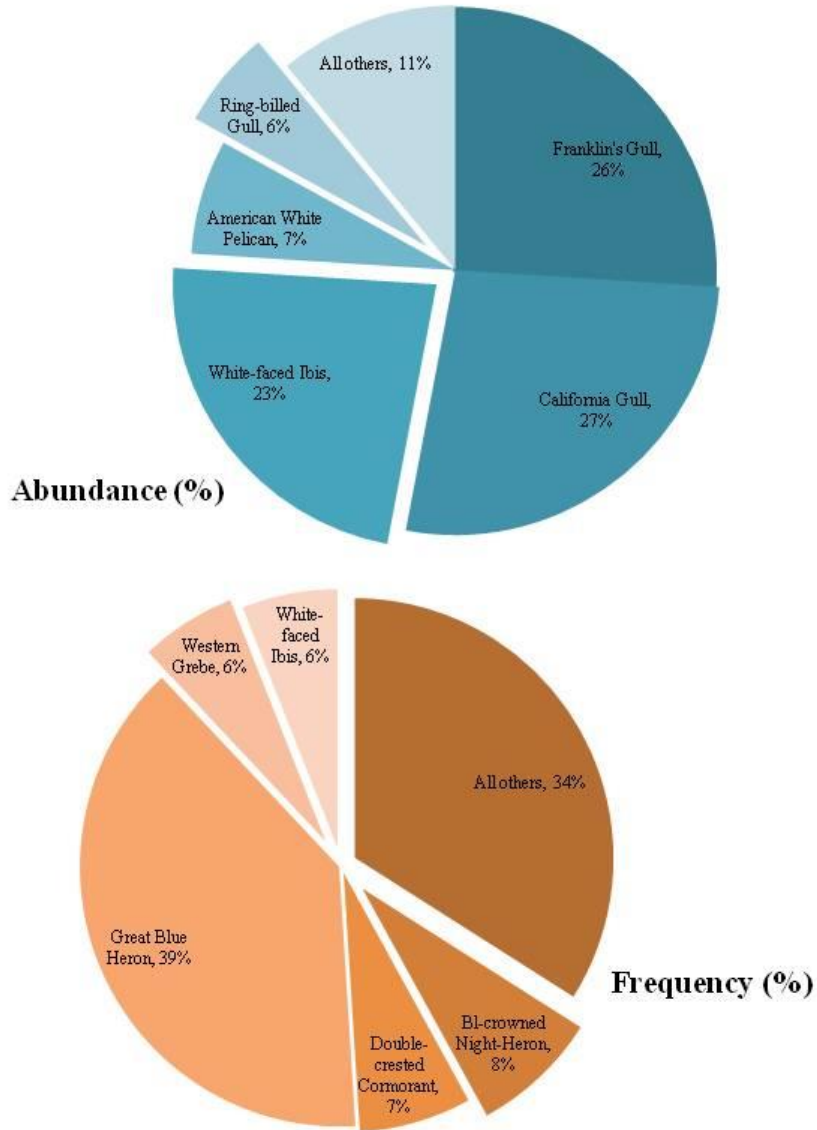

**Survey Type (ST).**--Survey method used to census or survey the colony. Codes were sometimes combined to indicate that more than one method was used.

<u>Code</u>	<u>Description</u>
A	Aerial survey from fixed-wing airplane or helicopter
AP	Aerial photography
B	Boat
C	Colony, ground survey in the colony or on the island
O	Overview, ground survey from a vantage point
U	Unknown

**Estimate Type (T).**--Type of estimate or count made by the observer. Codes may be qualitative or quantitative.

<u>Code</u>	<u>Description</u>
W	Direct Count
S	Known percent of colony. Exact count of birds, pairs, or nests in known fraction of colony area; count extrapolated to total number.
Z	Part estimated, part counted: exact count on part of colony area; remainder of colony and total number in colony estimated.
T	Count by groups: count of birds, pairs, or nests by groups (e.g., 10s or 1000s).
K	Count adjusted by observer: observer adjusted count of individuals, nests, pairs to give better estimate of total population (e.g., using study of attendance at nests).
Y	Estimate, not actual count: observer estimated birds, nests, or pairs by some other method.
X	Present, no count. Observer reported breeding birds of this species at colony, but no estimate of numbers.
P	Probable: observer reported breeding birds probably or possibly present at colony, but no numerical value.
V	Common or abundant: observer reported breeding birds common or abundant at colony, but no numerical estimate.
U	Type of estimate unknown: census method or accuracy of method unknown.

**Figure 2b.** Key to data tables and codes used in the maps in the *Atlas of Breeding Colonial Waterbirds in the Interior Western United States*.

**Figure 3.** Western Colonial Waterbird Survey summary (2009-2011). Relative abundance (top) and relative frequency (bottom) for the top colonial waterbird species across eight interior western U.S. states.
